Topic 11: Lasso And Beyond: Convex Learning

by Sai Zhang

Key points:

Disclaimer:

11.1 Lasso

Lasso (Least absolute Shrinkage and Selection Operator), proposed by Tibshirani (1996), aims to minimize the SSR (sum of residual squares) subject to the L1-norm (sum of the absolute value) of the coefficients being less than a constant.

11.1.1 Set up

For data $(\mathbf{x}_i, y_i)_{i=1}^n$, where

- y_i is the outcome for individual i

- $\mathbf{x}_i = (x_{i1}, \dots, x_{ip})'$ is the $p \times 1$ vector of predictors

Then the Lasso estimator $(\hat{\alpha},\hat{\beta})$ is defined as

$$\left(\hat{\alpha}, \hat{\boldsymbol{\beta}}\right) = \arg\min_{\alpha, \boldsymbol{\beta}} \left\{ \sum_{i=1}^{n} \left(y_i - \alpha - \sum_{j=1}^{p} \beta_j x_{ij} \right)^2 \right\}$$
 s.t.
$$\sum_{j=1}^{p} |\beta_j| \le t$$

for the $n \times 1$ response vector $\mathbf{y} = (y_1, \dots, y_n)'$, the $n \times p$ design matrix $\mathbf{X} = (\mathbf{x}_1, \dots, \mathbf{x}_n)'$ where $\mathbf{x}_i = (x_{i1}, \dots, x_{ip})'$ is a $p \times 1$ vector. Here $\hat{\alpha} = \overline{y}$, w.l.o.g., let $\overline{y} = 0$ and omit α for simplicity.

In matrix form, we have

• constrained form:

$$\hat{\boldsymbol{\beta}} = \arg\min_{\boldsymbol{\beta} \in \mathbb{R}^p} \left\{ \frac{1}{2n} \|\mathbf{y} - \mathbf{X}\boldsymbol{\beta}\|_2^2 \right\}$$
 s.t. $\|\boldsymbol{\beta}\|_1 \le t$

unconstrained form:

$$\hat{\boldsymbol{\beta}}(\lambda) = \arg\min_{\boldsymbol{\beta} \in \mathbb{R}^p} \left\{ \frac{1}{2n} \|\mathbf{y} - \mathbf{X}\boldsymbol{\beta}\|_2^2 + \lambda \|\boldsymbol{\beta}\|_1 \right\}$$

where the regularization parameter $\lambda \geq 0$:

-
$$\lambda \to \infty$$
: $\hat{\boldsymbol{\beta}}_{lasso} = \mathbf{0}$
- $\lambda = 0$: $\hat{\boldsymbol{\beta}}_{lasso} \to \hat{\boldsymbol{\beta}}_{OLS}$

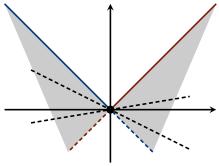

11.1.2 Solving Lasso

Lasso is essentially a quadratic optimization problem. Hence, the solution is given by taking the derivative (of the unconstrainted question) and set it equal to 0

$$\frac{\mathrm{d}}{\mathrm{d}\boldsymbol{\beta}} \left(\frac{1}{2n} \|\mathbf{y} - \mathbf{X}\boldsymbol{\beta}\|_{2}^{2} + \lambda \|\boldsymbol{\beta}\|_{1} \right) = 0$$

$$\Rightarrow \frac{1}{n} \underbrace{\mathbf{X}'}_{p \times n} \underbrace{\left(\mathbf{y} - \mathbf{X}\boldsymbol{\beta}\right)}_{=\epsilon, n \times 1} = \lambda \begin{cases} \mathrm{sign}\left(\beta_{j}\right), & \beta_{j} \neq 0 \\ [-1, 1], & \beta_{j} = 0 \end{cases}$$

this result follows the fact the L-1 norm $\|\beta\|$ is piecewise linear:

L1-norm (1-dimension)

For each component of the vector of the L-1 norm $f(\beta_i) = |\beta_i|$, we have:

- $\beta_i > 0$: $f'(\beta_i) = 1$
- $-\beta_{i} < 0$: $f'(\beta_{i}) = -1$
- $\beta_j = 0$: d $f \in [-1, 1]$ (shaded area) which gives the results stated above.

Take another look at this result

Proposition 11.1.1: Lasso Parameter Selection Rule

$$\frac{1}{n}\mathbf{X}'\left(\mathbf{y}-\mathbf{X}\boldsymbol{\beta}\right) = \frac{1}{n}\mathbf{X}'\boldsymbol{\epsilon} = \lambda \begin{cases} \operatorname{sign}\left(\beta_{j}\right), & \beta_{j} \neq 0 \\ [-1,1], & \beta_{j} = 0 \end{cases}$$

which gives a parameter selection criterion: for $\beta_j \neq 0$, $\operatorname{sign}(\beta_j)$ must agree with $\operatorname{Corr}(X_j, \epsilon)$, the correlation between the j-th variable X_j and (full-model) residuals $\epsilon = y - X\beta$.

11.1.3 Algorithm: from LARS to Lasso

Mathematically, Lasso is quite intuitive, but computionally, it can be quite consuming. Efron et al. (2004) propose an alogrithm that takes steps from a all-0 model to the biggest model (OLS), that is, **Least Angle Regression (LARS)**.

Intuition

The basic intuition of LARS is quite straight-forward: that is, covariates are considered from the highest corerlation with ${\bf v}$

echos a classic model-selection method, Forward Selection (forward stepwise regression):

11.2 Penalized Least Square Estimation

Lasso is one special class of Penalized Least Square (PLS) Estimation. For the linear regression model $\mathbf{y} = \mathbf{X}\boldsymbol{\beta} + \boldsymbol{\epsilon}$, if $\boldsymbol{\epsilon} \sim \mathcal{N}(\mathbf{0}, \sigma^2 \mathbf{I}_n)$, we have PLS as

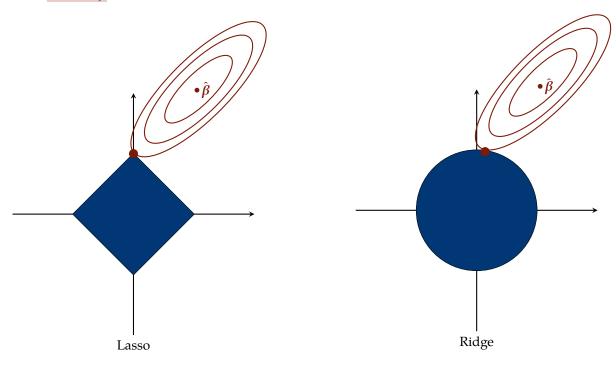

$$\min_{\boldsymbol{\beta} \in \mathbb{R}^p} \left\{ \frac{1}{2n} \|\mathbf{y} - \mathbf{X}\boldsymbol{\beta}\|_2^2 + \sum_{j=1}^p p_{\lambda} \left(|\beta_j| \right) \right\}$$

where $p_{\lambda}(\cdot)$ is a penalty function indexed by the regularization parameter $\lambda \geq 0$. Antoniadis and Fan (2001) showed that the PLS estimator $\hat{\beta}$ has the following properties:

- **sparsity**: if $\min_{t\geq 0} \{t + p'_{\lambda}(t)\} > 0$
- approximate unbiasedness: if $p'_{\lambda}(t) = 0$ for t large enough
- **continuity**: iff $\arg \min_{t\geq 0} \{t + p'_{\lambda}(t)\} = 0$

In general

- the **sigularity** of penalty function at the origin, $p'_{\lambda}(0_{+}) > 0$ is needed for generating **sparsity** in variable selection
- the **concavity** is needed to reduce the bias
