## Topic 15: Sparse Orthogonal Factor Regression

by Sai Zhang

Key points: Sparcity and dimensionality reduction for Multivariate Linear Regression models.

**Disclaimer**: The note is built on Prof. Jinchi Lv's lectures of the course at USC, DSO 607, High-Dimensional Statistics and Big Data Problems.

## 15.1 Motivation

Consider a Mutlivariate Linear Regression (MLR) model

$$\mathbf{Y}_{n\times q} = \mathbf{X}_{n\times p} \cdot \mathbf{C}_{p\times q} + \mathbf{E}_{n\times q}$$

How to apply regularization methods to this model? There are several approaches to consider

- Shrinkage: ridge regression to overcome multicollinearity
- sparsity: variable selection in multivariate setting
- Reduced-rank
  - Dimension reduction via reducing rank of C
  - $\min \|\mathbf{Y} \mathbf{XC}\|_F^2$  s.t.  $\operatorname{rank}(\mathbf{C}) \le r$
- Combinations
- **Low-rank** plus **sparse decomposition**: robust PCA, latent variable graphical models, covariance estimation
- Regularized matrix or tensor regression

Or, we can introduce a very attractive sparsity structure to achieve simultaneous dimension reduction and variable selection. This structure should be characterized by

- Having a few distinct channels/pathways relating responses and predictors
- Each of such associations may involve only a smaller subset, but not all of the responses and predictors

that is

This way, we can have

- Sparsity: selection of both latent and original variables
- Low-rank SVD: different subsets of responses allowed to be associated with different subsets of predictors

## Consider an example:

## Example 15.1.1: Dimension Reduction and Variable Selection via Sparse SVD

Consider the case where p = 1000, q = 100, then C, as a  $p \times q$  matrix, contains 100000 coefficients. Meanwhile, for a rank-3 SVD model:

$$\mathbf{C} = d_1 \mathbf{u}_1 \mathbf{v}_1' + d_2 \mathbf{u}_2 \mathbf{v}_2' + d_3 \mathbf{u}_3 \mathbf{v}_3'$$

where  $\mathbf{u}_1$ ,  $\mathbf{u}_2$ ,  $\mathbf{u}_3$  are all  $p \times 1$ , while  $\mathbf{v}_1$ ,  $\mathbf{v}_2$ ,  $\mathbf{v}_3$  are all  $q \times 1$ , hence, there are only  $3 \times (1000 + 100 + 1) = 3303$  paramaters to estimate. If futher assume sparcity, the dimension would be even lower.
