Topic 15: Sparse Orthogonal Factor Regression

by Sai Zhang

Key points: Sparcity and dimensionality reduction for Multivariate Linear Regression models.

Disclaimer: The note is built on Prof. Jinchi Lv's lectures of the course at USC, DSO 607, High-Dimensional Statistics and Big Data Problems.

15.1 Motivation

Consider a Mutlivariate Linear Regression (MLR) model

$$\mathbf{Y}_{n\times q} = \mathbf{X}_{n\times p} \cdot \mathbf{C}_{p\times q} + \mathbf{E}_{n\times q}$$

How to apply regularization methods to this model? There are several approaches to consider

- Shrinkage: ridge regression to overcome multicollinearity
- sparsity: variable selection in multivariate setting
- Reduced-rank
 - Dimension reduction via reducing rank of C
 - $\min \|\mathbf{Y} \mathbf{XC}\|_F^2$ s.t. $\operatorname{rank}(\mathbf{C}) \le r$
- Combinations
- **Low-rank** plus **sparse decomposition**: robust PCA, latent variable graphical models, covariance estimation
- Regularized matrix or tensor regression

Or, we can introduce a very attractive sparsity structure to achieve simultaneous dimension reduction and variable selection. This structure should be characterized by

- Having a few distinct channels/pathways relating responses and predictors
- Each of such associations may involve only a smaller subset, but not all of the responses and predictors

that is

This way, we can have

- **Sparsity**: selection of both <u>latent</u> and <u>original</u> variables
- Low-rank SVD: different subsets of responses allowed to be associated with different subsets of predictors

Consider an example:

Example 15.1.1: Dimension Reduction and Variable Selection via Sparse SVD

Consider the case where p = 1000, q = 100, then C, as a $p \times q$ matrix, contains 100000 coefficients. Meanwhile, for a rank-3 SVD model:

$$\mathbf{C} = d_1 \mathbf{u}_1 \mathbf{v}_1' + d_2 \mathbf{u}_2 \mathbf{v}_2' + d_3 \mathbf{u}_3 \mathbf{v}_3'$$

where for \mathbf{u}_1 , \mathbf{u}_2 , \mathbf{u}_3 ,
