# Topic 18: Eigenvalue and Spike Models

by Sai Zhang

Key points: .

**Disclaimer**: The note is built on Prof. Jinchi Lv's lectures of the course at USC, DSO 607, High-Dimensional Statistics and Big Data Problems.

#### 18.1 Motivation

Consider n independent observations  $\mathbf{X}_i \in \mathbb{R}^p$  drawn from a  $\mathcal{N}(\mathbf{0}, \mathbf{\Sigma})$ , then the covariance can be decomposed into 2 parts, white noise and low rank

$$\Sigma = \text{Cov}(\mathbf{X}_i) = \mathbf{I} + \sum_{k=1}^{M} \theta_k \nu_k \nu_k' = \Sigma_0 + \mathbf{\Phi}$$

where M denotes the **number of spikes** in the distribution of eigenvalues. The idea is: spikes deviate from a reference model along a <u>small fixed number</u> of unknown directions. If  $\Phi = 0$ , then none of the sample eigenvalues is separated from the bulk.

**Why a spike model is interesting?** A spike model can help determine the latent dimension of the data, some examples being

- Principal component analysis (PCA): spikes are related to the directions of the most variations of the data, i.e., the principal components
- Clustering model: M spikes is equivalent to M+1 clusters
- Economic significance: *M* is related to the number of factor loadings

Then the question is threefold:

- How to determine *M*
- How to estimate  $v_k$
- How to test  $\theta_k$

Under rank one alternative, we would like to test the hypothesis

$$H_1: \mathbf{\Sigma} = \mathbf{I}_p + \theta \mathbf{\nu} \mathbf{\nu}', \theta > 0$$

against the null

$$H_0: \mathbf{\Sigma} = \mathbf{I}_p$$

with the key assumptions:

A1 Gaussian error

A2 large  $p: p \le n$  but allows  $p/n \to \gamma \in (0,1)$ 

Under these assumptions, for the  $n \times p$  data matrix  $\mathbf{X} = (\mathbf{X}'_1 \cdots \mathbf{X}'_n)'$ ,  $\mathbf{X}'\mathbf{X}$  has a p-dimensional **Wishart** distribution  $W_p(n, \Sigma)$  with the degree of freedom n and covariance matrix  $\Sigma$ , which is a *random matrix*.

If  $\mathbf{Y} = \mathbf{M} + \mathbf{X}$ , that is, the sum of the *random matrix*  $\mathbf{X}$  and a *deterministic matrix*  $\mathbf{M}$  (also  $n \times p$ ), then  $\mathbf{Y}'\mathbf{Y}$  has a p-dimensional Wishart distribution  $W_p(n, \Sigma, \Psi)$  with n degrees of freedom, covariance matrix  $\Sigma$  and non-centrality matrix  $\mathbf{\Psi} = \Sigma^{-1}\mathbf{M}'\mathbf{M}$ .

## Definition 18.1.1: Density of Wishart Distribution

The PDF of Wishart distribution is defined as

$$f(\mathbf{X}) = \frac{1}{2^{np/2} \Gamma_p\left(\frac{n}{2}\right) |\mathbf{\Sigma}|^{n/2}} |\mathbf{X}|^{(n-p-1)/2} \exp\left(-\frac{1}{2} \operatorname{tr}\left(\mathbf{\Sigma}^{-1} \mathbf{X}\right)\right)$$

where **X** is a symmetric positive semidefinite and  $\Gamma_p\left(\frac{n}{2}\right)$  is a multivariate gamma function such that

$$\Gamma_p\left(\frac{n}{2}\right) = \pi^{\frac{p(p-1)}{4}} \prod_{j=1}^p \Gamma\left(\frac{n}{2} - \frac{j-1}{2}\right)$$

Notice that the sample covariance matrix  $S = \frac{1}{n}X'X$  is just a scaled version of Wishart distribution

$$n\mathbf{S} = \mathbf{X}'\mathbf{X} \sim W_n(n, \mathbf{\Sigma})$$

For  $\Sigma = \mathbf{I}_p$ , the empirical distribution fo eigenvalues converges to Marcenko-Pastur distribution

$$f^{\text{MP}}(x) = \frac{1}{2\pi\gamma x} \sqrt{(b_+ - x)(x - b_-)}$$

where  $b_{\pm} = (1 \pm \sqrt{\gamma})^2$ . Then:

• under  $H_0: \Sigma = \mathbf{I}_p$ , we have

$$n^{2/3} \left( \frac{\lambda_1 - \mu(\gamma)}{\sigma(\gamma)} \right) \stackrel{d}{\to} TW_1$$

where TW<sub>1</sub> is the Tracy-Widom distribution

• under  $H_1: \Sigma = \mathbf{I}_p + \theta \nu \nu', \theta > 0$ , if  $\theta$  is strong  $(\theta \gg \sqrt{\gamma})$ , then

$$n^{1/2}\left(\frac{\lambda_1-\rho(\theta,\gamma)}{\tau(\theta,\gamma)}\right) \xrightarrow{d} \mathcal{N}(0,1)$$

Here, the largest eigenvalue test is the best test. **But** when the signal is weak  $(0 \le \theta < \sqrt{\gamma})$ , the largest eigenvalue under the alternative converges to the same distribution as null:

$$n^{2/3} \left( \frac{\lambda_1 - \rho(\theta, \gamma)}{\tau(\theta, \gamma)} \right) \xrightarrow{d} TW_1$$

which means that the largest eigenvalue test *fails*. On top of this, **resampling** also fails when p is large. Next, we develop another test to cope with these problems.

Figure 18.1: Failure of Resampling Test (n = p = 100)

# 18.2 Johnstone and Onatski (2020)

Consider the basic equation of classical multivariate statistics:

$$\det\left(\mathbf{H} - \mathbf{x}\mathbf{E}\right) = 0\tag{18.1}$$

with  $p \times p$  matrices

$$n_1\mathbf{H} = \sum_{k=1}^{n_1} \mathbf{x}_k \mathbf{x}'_k$$
 hypothesis SS
$$n_1\mathbf{E} = \sum_{k=1}^{n_1} \mathbf{z}_k \mathbf{z}'_k$$
 error SS

The solution  $\mathbf{x}$  is generalized eigenvalues  $\{\lambda_i\}_{i=1}^p$ , which are the eigenvalue of  $\mathbf{F}$ -ratio  $\mathbf{E}^{-1}\mathbf{H}$ . Johnstone and Onatski (2020) summarized 5 topics using  $\mathbf{E}^{-1}\mathbf{H}$  relying on the five most common hypergeometric functions  $\mathbf{E}^{-1}\mathbf{H}$  relying on the five most common hypergeometric functions  $\mathbf{E}^{-1}\mathbf{H}$  relying on the five most common hypergeometric functions  $\mathbf{E}^{-1}\mathbf{H}$ 

• scalar inputs

$${}_{\mathbf{p}}\mathcal{F}_{\mathbf{q}}(a,b;x) = \sum_{k=0}^{\infty} \frac{(a_1)_k \cdots (a_p)_k}{(b_1)_k \cdots (b_p)_k} \frac{x^k}{k!}$$

where  $(a_i)_k$  are generalized Pochhammer symbols

- single matrix inputs, where  $\boldsymbol{S}$  is symmetric and usually diagonal

$${}_{\mathbf{p}}\mathcal{F}_{\mathbf{q}}(a,b;\mathbf{S}) = \sum_{k=0}^{\infty} \sum_{\kappa} \frac{(a_1)_{\kappa} \cdots (a_p)_{\kappa}}{(b_1)_{\kappa} \cdots (b_p)_{\kappa}} \frac{C_{\kappa}(\mathbf{S})}{k!}$$

where  $C_k$  are the zonal polynomials. Easily,  $_0\mathcal{F}_0(\mathbf{S}) = e^{\operatorname{tr}(\mathbf{S})}, _1\mathcal{F}_0(a,\mathbf{S}) = |\mathbf{I} - \mathbf{S}|^{-a}$ 

- two matrix inputs, where  $\boldsymbol{S},\boldsymbol{T}$  are both symmetric

$$_{\mathbf{p}}\mathcal{F}_{\mathbf{q}}(a,b;\mathbf{S},\mathbf{T}) = \int_{O(p)} {}_{\mathbf{p}}\mathcal{F}_{\mathbf{q}}(a,b;\mathbf{SUTU'})(d)\mathbf{U}$$

<sup>&</sup>lt;sup>1</sup>Hypergeometric functions are:

		Statistical method	$n_1\mathbf{H}$	$n_2\mathbf{E}$	Univariate Analog
$_0\mathcal{F}_0$	PCA	Principal components analysis	$W_p(n_1, \Sigma + \Phi)$	$n_2\Sigma$	$\chi^2$
$_1\mathcal{F}_0$	SigD	Signal detection	$W_p(n_1, \Sigma + \Phi)$	$W_p(n_2, \Sigma)$	non-central $\chi^2$
$_0\mathcal{F}_1$	$REG_0$	Multivariate regression, with known error	$W_p(n_1, \Sigma, n_1\mathbf{\Phi})$	$n_2\Sigma$	F
$_1\mathcal{F}_1$	REG	Multivariate regression, with unknown error	$W_p(n_1, \mathbf{\Sigma}, n_1\mathbf{\Phi})$	$W_p(n_2, \Sigma)$	non-central F
$_2\mathcal{F}_1$	CCA	Canonical correlation analysis	$W_p(n_1, \mathbf{\Sigma}, \mathbf{\Phi}(\mathbf{Y}))$	$W_p(n_2, \Sigma)$	$\frac{r^2}{1-r^2}$

Table 18.1: 5 Statistical Methods

For  $_0\mathcal{F}_0$  and  $_0\mathcal{F}_1$ , **E** is deterministic,  $\Sigma$  is known,  $n_2$  disppears, otherwise **E** is independent of **H**.

## 18.2.1 Definitions and global assumptions

Let **Z** be an  $n \times p$  data matrix with rows (observations) drawn **i.i.d.** from  $\mathcal{N}_p(\mathbf{0}, \Sigma)$ , and a deterministic matrix **M** of  $n \times p$ , then for  $\mathbf{Y} = \mathbf{M} + \mathbf{Z}$ ,

- $\mathbf{H} = \mathbf{Y}'\mathbf{Y}$  has a p dimensional Wishart distribution  $W_p(n, \Sigma, \Psi)$  with n degrees of freedom, covariance matrix  $\Sigma$  and non-centrality matrix  $\Psi = \Sigma^{-1}\mathbf{M}'\mathbf{M}$
- the corresponding central Wishart distribution with  $\mathbf{M} = \mathbf{0}$  is  $W_v(n, \Sigma)$

Johnstone and Onatski (2020) assume a relative low dimensionality  $p \le \min\{n_1, n_2\}$  where  $n_1, n_2$  are the degrees of freedom as in Table 18.1, where

- $p \le n_2$  ensures almost sure invertibility of matrix **E** in Equation 18.1
- $p \le n_1$  is not essential, but reduces the number of various situations of consideration.

### 18.2.2 5 classes of problems

With these assumptions, they established a unified statistical problem **symmetric matrix denoising (SMD)** that can be linked to the 5 classes of problems:

**PCA**  $n_1$  i.i.d. observations drawn from  $\mathcal{N}_p(\mathbf{0}, \mathbf{\Omega})$  to test the hull hypothesis that the population covariance  $\mathbf{\Omega} = \mathbf{\Sigma}$ , with the alternative of interest being

$$\Omega = \Sigma + \Phi$$
, with  $\Phi = \theta \phi \phi'$ 

where  $\theta > 0$ ,  $\phi$  are unknown, and  $\phi$  is normalized s.t.  $\|\Sigma^{-1/2}\phi\| = 1$ . W.L.O.G., assume  $\Sigma = \mathbf{I}_p$ , then under the alternative, the first principal component explains a larger portion of the variation than the other principal components. Re-formulate the hypotheses in terms of the spectral *spike* parameter  $\theta$ , we have

$$H_0: \theta_0 = 0$$
  $H_1: \theta_0 = \theta > 0$  (18.2)

where  $\theta_0$  is the true value of the *spike*. A **maximal invariant statistic** consists of the solutions  $\lambda_1 \ge \cdots \ge \lambda_p$  of Equation 18.1 with

- *n*<sub>1</sub>**H** equal to the sample covariance matrix
- $\mathbf{E} = \mathbf{\Sigma}$

**SigD** Now consider testing the **equality** of covariance matrices **Ω** and **Σ**, corresponding to 2 independent p-dimensional mean-zero Gaussian samples of size  $n_1$  and  $n_2$ , with the alternative still

$$\Omega = \Sigma + \Phi$$
, with  $\Phi = \theta \phi \phi'$ 

and again, assume  $\Sigma = I_p$  (but NOT necessarily known), here, instead of Equation 18.1, consider

$$\det\left(\mathbf{H} - \lambda \left(\mathbf{E} + \frac{n_1}{n_2}\mathbf{H}\right)\right) = 0 \tag{18.3}$$

naturally, SigD reduces to PCA as  $n_2 \rightarrow \infty$  while  $n_1$  and p held constant.

**REG**<sub>0</sub> Next, consider a linear regression with multivariate response

$$Y = X\beta + \epsilon$$

with known covariance matrix  $\Sigma$  of the i.i.d. Gaussian rows of the error matrix  $\epsilon$ . Here, to test linear restrictions on the matrix of coefficients  $\beta$ , we can split the matrix of transformed response variables Y into 3 parts  $Y_1$ ,  $Y_2$ ,  $Y_3$ , where

•  $\mathbf{Y}_1$  is  $n_1 \times p$  where p is the number of response variables,  $n_1$  is the number of linear restrictions (per each of the p columns of matrix  $\boldsymbol{\beta}$ ), under the null  $H_0$ :  $\mathbb{E}\mathbf{Y}_1 = 0$ , versus the alternative

$$\mathbb{E}\mathbf{Y}_1 = \sqrt{n_1 \theta} \boldsymbol{\psi} \boldsymbol{\phi}' \tag{18.4}$$

where  $\theta > 0$ ,  $\left\| \mathbf{\Sigma}^{-1/2} \boldsymbol{\phi} \right\| = 1$  and  $\left\| \boldsymbol{\psi} \right\| = 1$ 

- $\mathbf{Y}_2$  is  $(q n_1) \times p$ , where q is the number of regressors
- $\mathbf{Y}_3$  is  $(T q) \times p$ , where T is the number of observations

In this case, tests can be based on the solutions  $\lambda_1, \dots, \lambda_p$  to

$$\det(\mathbf{H} - \lambda \mathbf{E}) = \mathbf{0}$$

where  $\mathbf{H} = \mathbf{Y}_1'\mathbf{Y}_1/n_1$  and  $\mathbf{E} = \mathbf{\Sigma}$ . The solutions represent a multivaraite analog of the difference between the sum of squared residuals in the restircted and unrestricted regressions. Under the null,  $n_1\mathbf{H}$  is distributed as  $W_p(n_1, \mathbf{\Sigma})$ . Here,

$$n_1 \mathbf{H} \sim W_p(n_1, \Sigma)$$
 under  $H_0$   
 $n_1 \mathbf{H} \sim W_p(n_1, \Sigma, n_1 \Phi)$ , where  $\Phi = \theta \Sigma^{-1} \phi \phi'$  under  $H_1$ 

Again, W.L.O.G, assume  $\Sigma = \mathbf{I}_p$ . This **canonical form** of REG<sub>0</sub> is essentially equivalent to the setting of **matrix denoising** 

$$Y_1 = M + Z$$

**REG** Again, consider the linear regression

$$Y = X\beta + \epsilon$$

but NOT knowing the covariance matrix  $\Sigma$  of rows of  $\epsilon$ . Here, the solutions again solve  $\det(H - \lambda E) = 0$  with

$$\mathbf{H} = \mathbf{Y}_1' \mathbf{Y}_1 / n_1, \ \mathbf{E} = \mathbf{Y}_3' \mathbf{Y}_3 / n_2$$

this represents a multivariate analog of the F ratio: the difference between the sum of squared residuals in the restricted and unrestricted regressions to the sum of squared residuals in the restricted regression. Again, as  $n_2 \to \infty$ , REG reduces to REG<sub>0</sub>.

**CCA** Consider testing for independence between Gaussian vectors  $x_t \in \mathbb{R}^p$  and  $y_t \in \mathbb{R}^{n_1}$ , given zero-mean observations with  $t = 1, \dots, n_1 + n_2$ . Partition the population and sample covariance matrices of the observations  $(x'_t, y'_t)'$  into

$$\begin{pmatrix} \Sigma_{xx} & \Sigma_{xy} \\ \Sigma_{yx} & \Sigma_{yy} \end{pmatrix} \qquad \begin{pmatrix} \mathbf{S}_{xx} & \mathbf{S}_{xy} \\ \mathbf{S}_{yx} & \mathbf{S}_{yy} \end{pmatrix}$$

respsectively. Under  $H_0: \Sigma_{xy} = \mathbf{0}$ , while the alternative is

$$\Sigma_{xy} = \sqrt{\frac{n_1 \theta}{n_1 \theta + n_1 + n_2}} \phi \psi' \tag{18.5}$$

where the nuisance parameters  $\phi \in \mathbb{R}^p$  and  $\psi \in \mathbb{R}^{n_1}$  are normalized s.t.

$$\left\|\boldsymbol{\Sigma}_{xx}^{-1/2}\boldsymbol{\phi}\right\| = \left\|\boldsymbol{\Sigma}_{yy}^{-1/2}\boldsymbol{\psi}\right\| = 1$$

And the test can be based on the squared sample canonical correlations  $\lambda_1, \cdots, \lambda_p$  that solves

$$\det\left(\mathbf{H} - \lambda \mathbf{E}\right) = \mathbf{0}$$

with

$$\mathbf{H} = \mathbf{S}_{xy} \mathbf{S}_{yy}^{-1} \mathbf{S}_{yx}$$
 
$$\mathbf{E} \mathbf{S}_{xx}$$

#### 18.2.3 SMD

For a  $\mathbf{X} = \mathbf{\Phi} + \mathbf{Z}/\sqrt{p}$  where  $\mathbf{Z}$  is a noise matrix from the **Gaussian Orthogonal Ensemble** (GOE)<sup>2</sup> We seek to make inference about a symmetric rank-one *signal* matrix  $\mathbf{\Phi} = \theta \phi \phi'$ . The null and the alternative is again as in 18.2. The nuisance vector  $\boldsymbol{\phi} \in \mathbb{R}^p$  is normalized s.t.  $\|\boldsymbol{\phi}\| = 1$ .

The problem remains **invariant** under the multiplication of X from the left by an orthogonal matrix, and from the right by its transpose. A maximal invariant statistic consists of the solutions  $\lambda_1, \dots, \lambda_p$  to  $\det(H - \lambda E) = 0$  with H = X and  $E = I_p$ .

SMD can be viewed as a degenerate version of the 5 classes of problems, as shown in Figure 18.2:

- SMD, PCA, REG<sub>0</sub>: random H and deterministic E
- PCA and SigD are parallel to REG<sub>0</sub>
- CCA has a different structure of H and E

#### 18.2.4 The likelihood ratios

The goal is to study the asymptotic behavior of likelihood ratios based on the observed eigenvalues

$$\Lambda = \operatorname{diag}\left\{\lambda_1, \cdots, \lambda_p\right\}$$

$$\mathbf{Z}_{ii} \sim \mathcal{N}(0,2)$$

$$\mathbf{Z}_{ij} \sim \mathcal{N}(0,1)$$
 if  $i > j$ 

<sup>&</sup>lt;sup>2</sup>**Z** is from the GOE that it is **symmetric** and

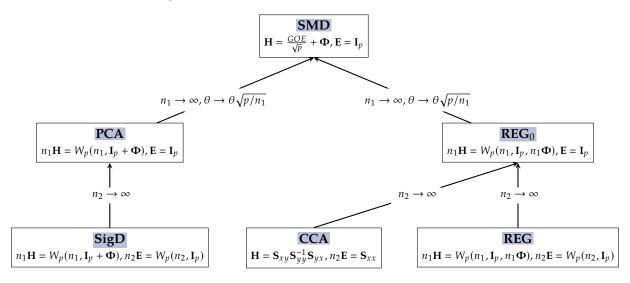

Figure 18.2: SMD and 5 Classes of Statistical Problems

then the likelihood of the alternative versus the null is given by

$$\mathcal{L}(\theta, \Lambda) = \frac{p(\Lambda; \theta)}{p(\Lambda; 0)} = \alpha(\theta)_{p} \mathcal{D}_{q}(\mathbf{a}, \mathbf{b}; \mathbf{\Phi}, \Lambda)$$
(18.6)

where  $\Phi = \Phi(\theta)$  is a *p*-dimensional matrix diag  $\{\Phi_{11}, 0, \dots, 0\}$ . Consider the hypergeometric functions of 2 matrix arguments  $\Phi$ ,  $\Lambda$  are defined as

$${}_{p}\mathcal{F}_{q}(\mathbf{a},\mathbf{b};\mathbf{\Phi},\mathbf{\Lambda}) = \sum_{k=0}^{\infty} \frac{1}{k!} \sum_{\kappa-k} \frac{(a_{1})_{\kappa} \cdots (a_{p})_{\kappa}}{(b_{1})_{\kappa} \cdots (b_{1})_{\kappa}} \frac{C_{\kappa}(\mathbf{\Phi})C_{\kappa}(\mathbf{\Lambda})}{C_{\kappa}(\mathbf{I}_{p})}$$

where  $\mathbf{a} = (a_1, \dots, a_p)$  and  $\mathbf{b} = (b_1, \dots, b_q)$  are parameters,  $\kappa$  are partitions of the integer k,  $(a_j)_{\kappa}$  and  $(b_i)_{\kappa}$  are the generalized Pochhammer symbols,  $C_{\kappa}$  are the zonal polynomials. For each of the 6 classes of problems, we have the parameters as in Table where  $n = n_1 + n_2$ .

Table 18.2: Parameters of the Likelihood Ratios in Eq.18.6

Classes	$_{ m p}\mathcal{F}_{ m q}$	$\alpha(\theta)$	а	b	$\mathbf{\Phi}_{11}$
SMD	$_0\mathcal{F}_0$	$\exp(-p\theta^2/4)$	-	-	$\theta p/2$
PCA	$_0\mathcal{F}_0$	$(1+\theta)^{-n_1/2}$	-	-	$\theta n_1/(2(1+\theta))$
SigD	$_1\mathcal{F}_0$	$(1+\theta)^{-n_1/2}$	-	-	$\theta n_1/(n_2(1+\theta))$
$REG_0$	$_0\mathcal{F}_1$	$\exp(-n_1\theta/2)$	-	$n_1/2$	$\theta n_1^2/4$
REG	$_1\mathcal{F}_1$	$\exp(-n_1\theta/2)$	n/2	$n_1/2$	$\theta n_1^2/(2n_2)$
CCA	$_2\mathcal{F}_1$	$(1+n_1\theta/n)^{-n/2}$	(n/2, n/2)	$n_1/2$	$\theta n_1^2/(n_2^2 + n_2 n_1 (1 + \theta))$

Some links in Fig. 18.2 can also be established via asymptotic relations between hypergeometric functions.
